Determine the short-circuit current (IsubSC) at the transformer's secondary terminals per its impedance. IsubSC = (100% / %ZsubT) x IsubS = (100/2.5) \* 417 = 16,680A. Therefore, the OCPD must be capable of safely interrupting this amount of current, along with the asymmetrical current value (usually a multiplier times the symmetrical value).

The motor starting reactance is must often used for short-circuit calculation. However, the resistance to be used for short-circuit calculations is lower than the starting resistance provided on the data sheet. Unless a short-circuit resistance is provided, typical motor X/R ratio curves can be used.

The transformer short circuit current is calculated as follows:  $I_{faul} t a c t u a l = S b a s e \times 100 \div 3 \times V b a s e \times Z \%$ . where  $I_{faul} t a c t u a l$  is in kA,  $S b a s e$  is in kVA,  $V b a s e$  is in V, and  $Z \%$  is in percentage. This is basically a combination of the steps in the per-unit calculation method:

Short Circuit Current Calculation Example The full-load current of a building power distribution system is 1200 A. The building is served by a single transformer having 5 percent impedance. The utility power service supplying the transformer is from a nearby substation with practically unlimited power.

Short-circuit calculations are performed because of several reasons. In short-circuit studies, generally, different characteristic values of short-circuit current e.g. peak short-circuit current (ip), equivalent thermal short-circuit current (Ith), etc. are calculated.

A simple method for the approximation of short circuit currents is the infinite bus short circuit calculation method. This method calculates the worst possible or maximum current that propagates from the transformer in case of a short circuit.

The calculation of short-circuit currents in d.c. auxiliary installations, e.g., in power plants and substations is dealt with in IEC 61660-1. Contrary to the approach for the calculation of short-circuit currents in a.c. three-phase systems, the determination of the exact time course of the short-circuit current is needed besides the calculation of defined parameters [42].

The generator short circuit fault current calculator uses a simplified method to calculate the fault current from the following parameters: Rated (Ur). The rated phase-to-phase voltage of the generator in V. Rating (Sr). The rating power of the generator in kVA. Impedance (Zk). The short circuit impedance of the generator as a percentage.

When you apply these requirements to a circuit breaker, you must calculate the maximum 3-phase fault current the breaker will be required to interrupt. This current can be defined as the short-circuit current available at the terminals of the protective device. You can assume that 3-phase short circuits are “bolted,” or have no impedance.
