To do stoichiometry, start by balancing the chemical equation so that the number of atoms on each side of the equal sign are exactly the same. Next, convert the units of measurement into moles and use the mole ratio to calculate the moles of substance yielded by the chemical reaction.

Yes stoichiometry can even be used with thermodynamics. It shows the movement of energy through out a reaction. There is two types of energy that can used. There is enthalpy (heat), or free energy. Entropy (randomness) can also be used. Free energy is just the combination of entropy and enthalpy. There are two ways you find these.

Stoichiometry The atomic ratios in each compound are also the relative number of atomic mass units of its elements. The first example is nitrous oxide (N_2O), as shown in Table 1. The relative masses were obtained by multiplying the atomic ratios and atomic masses.

Stoichiometric Guides The branch of stoichiometry deals with the calculation of various quantities of reactants or products of a chemical reaction. The word “stoichiometry” itself is derived from two Greek words “stoichion” that means element and “metry” means to measure. We have the following two sub-sections in this concept of stoichiometry.

In lay terms, the stoichiometric coefficient (or stoichiometric number in the IUPAC nomenclature) of any given component is the number of molecules that participate in the reaction as written. For example, in the reaction $CH_4 + 2 O_2 \rightarrow CO_2 + 2 H_2O$, the stoichiometric coefficient of CH_4 is 1, the stoichiometric coefficient of O_2 is 2, for CO_2

The stoichiometric mixture for a gasoline engine is the ideal ratio of air to fuel that burns all fuel with no excess air. For gasoline fuel, the stoichiometric air–fuel mixture is about 14.7:1 i.e. for every one gram of fuel, 14.7 grams of air are required. For pure octane fuel, the oxidation reaction is:
