A variable speed motor enables you to control the speed at which it operates. The motor may use an internal rheostat, or may have several speed settings which you select using a switch on the motor. Wiring a variable speed motor is the same as wiring a single speed motor, as the speed control function is an integral part of the motor. Therefore, you only need to connect two wires to the motor's terminals.

Wiring diagram: variable speed fan motor contains five terminals (1,2...5) as shown at the fig, the red winding is the main winding while the black one is the auxiliary winding, terminals 1&2 connected to the capacitor, terminals 3,4&5 are the second end of the main winding so that by selecting the speed desired by fan controller it will connect L2 (supply second end) to 3 or 4 or 5 (main winding second end), note that supply terminal is connected with the capacitor end (2) as shown.

The premise of this speed controller is to add the male and female ends of an extension cord to a variable controller (light dimmer). All you are really doing is splicing in the controller between the extension cord. If you really wanted to, you could just add the dimmer to the live wire on the extension cord and that would be that.

Variable speed ECM (Electronically commutated motor) are motors that are powered by a variable frequency. In essence the motor control takes the incoming electrical frequency and converts it to a new frequency (cycle rate) that no longer needs to be 60hz. This control over the actual frequency is what makes ECM motors so much more variable in ten speeds they can run. So in summary. There are three way you can change a motor speed.
