Vector Control of an Induction motor – The sole idea behind the vector control of induction motor is to have an electrical drive which must offer superior performance than widely used separately excited dc motor in industry. Further such a drive should also emerge as a robust, reliable, maintenance free and cheaper alternative of dc drive.

In case of induction motor vector control, the d-axis is aligned along the rotor flux axis, which implies, $i_{rq} = 0$. For the motor under consideration, squirrel cage induction motor where the rotor bars are shorted, the rotor voltage v_{sd} and v_{sq} are both zero. Substituting these and combining the d and q equation, leads to the following simplified equations:

Vector control, also called field-oriented control, is a variable-frequency drive control method in which the stator currents of a three-phase AC electric motor are identified as two orthogonal components that can be visualized with a vector. One component defines the magnetic flux of the motor, the other the torque.

Vector Control of Three Phase Induction Motor

Since the speed of an induction motor in rev. per minute is given by: $N = 120 f P (1 - s) / (3.1)$ Where f = frequency of supply, P = number of poles, and s = slip. Thus the speed of the motor can be changed by controlling the frequency, or number of poles or the slip. Since, number of poles of a motor is fixed at the time of construction, special motors are required with provision of pole changing windings.

Vector Control of AC Induction Motors - SlideShare

With vector control, the mechanically robust induction motors can be used in high-performance applications where dc motors were previously used. The key feature of the control scheme is the orientation of the synchronously rotating q-d-0 frame to the rotor flux vector.

Vector Control - an overview | ScienceDirect Topics

Vector control, also called field-oriented control, is a variable-frequency drive control method in which the stator currents of a three-phase AC electric motor are identified as two orthogonal components that can be visualized with a vector. One component defines the magnetic flux of the motor, the other the torque. The control system of the drive calculates the corresponding current component references from the flux and torque references given by the drive's speed control. Typically proportio

Squirrel-cage induction motors fed VSI is standard in traction applications. Scalar control technique controls the parameter of Amplitude of voltage. Output torque of IM is dependent on the square of terminal voltage. Now to increase torque an increase in voltage is done in voltage control technique.

Space vectors of the stator voltage and current and magnetic fluxes (flux linkages) are commonly employed in the analysis and control of induction motor adjustable-speed drives. The space vectors are obtained by an invertible, static, abc → dq, transformation of phase variables. The vector notation is used in dynamic equations of the motor.

In FOC, the principle of decoupled torque and flux control are applied and it relies on the instantaneous control of stator current space vectors. Control of induction motor is complicated due to the control of decoupled torque and flux producing components of the stator phase currents.

FIELD ORIENTED CONTROL OF INDUCTION MOTOR

In induction motor control concepts where V/Hz technique is employed, the speed control is implemented by adjusting the stator voltage with respect to frequency such that the air gap flux is never able to deviate beyond the expected range of the steady-state, in other words it is maintained within this estimated steady-state value, and hence it is also called the scalar control method since the technique heavily depends on the steady-state dynamics for controlling the motor speed.
